

# The impact of flow rate on flow batteries

### **Overview**

Does flow rate affect battery power?

The flow rate of the battery directly affects the pressure losses that occur and, by extension, the power that the pumps must provide for the battery to operate. However, as studies such as Ref. 20 have reported, flow rate also influences battery voltage and shunt currents, thus affecting the battery power.

How does flow factor affect battery efficiency?

Linking with Eq. 22, the higher the current, the greater the flow rate needed; therefore, the pressure losses will increase, implying a higher need for pump power. This probably directly limits the value of the flow factor. Knowing the optimum flow factor for battery operation is of great interest to optimize battery efficiency.

Does electrolyte flow rate affect battery performance?

The battery was tested to assess its performance; it achieved a coulombic efficiency of 97%, a voltage efficiency of 74.5% and an energy efficiency of 72.3%. The battery was used to study the effect of electrolyte flow rate on the overall performance. The results indicated that an increased flow rate increased the capacity.

Does variable flow rate affect battery capacity?

Effect of variable flow rate on capacity Despite the increased battery capacity that can be achieved at high flow rates, greater levels of pumping reduce the overall efficiency of the system (battery, pumps and tubings).

What factors affect battery efficiency?

In addition, a PSO type technique is introduced to optimize the battery design. Neither study considers activation and concentration overpotentials. One factor that critically affects battery efficiency is the flow rate. The flow rate is

related to the charge or discharge current of the battery and the electrolyte flow rate.

Does a high flow rate increase battery capacity?

Increasing the flow rate improves the charge and discharge capacities of the battery, but this improvement tends to be smaller beyond a stoichiometric number of 9. This indicates that there is a saturation point close to  $\lambda=9$  beyond which no significant increase in capacity can be achieved.
